## Abstract

**Purpose:** The aim of this prospective clinical study was to evaluate the survival rate of narrow diameter implants (NDI) compared to regular diameter implants (RDI) installed in the posterior region of the jaw after a one-year follow-up.

**Materials and Methods:** Twenty-four patients received 24 implants, 12 NDI and 12 RDI, installed in the posterior region of the jaw. Implant stability was evaluated by resonance frequency analysis (RFA) and periotest values (PTV) at the time of implant placement and after 6 months and 1 year of loading. Marginal bone loss was evaluated by radiographic examination at 6 months and 1 year after implant placement.

**Results:** The survival rate was 100% for both groups. The mean RFA values were 70.5 ± 4.5 for NDI and 71.5 ± 4.5 for RDI. The mean PTV values were -3.5 ± 1.5 for NDI and -3.5 ± 1.5 for RDI. The mean marginal bone loss was 0.5 ± 0.5 mm for NDI and 0.5 ± 0.5 mm for RDI.

**Conclusion:** The results of this study showed that narrow diameter implants can be used in the posterior region of the jaw with predictable results.

## Keywords

Narrow diameter implant; Resonance frequency analysis; Periotest

## Introduction

The placement of dental implants in the posterior region of the jaw is a predictable treatment option for the rehabilitation of partially edentulous patients [1-3]. However, the anatomical limitations of the posterior region of the jaw, such as the presence of the maxillary sinus and the mandibular canal, can make implant placement difficult [4,5]. Bone augmentation procedures are frequently required to increase the volume of bone available for implant placement [6,7]. However, these procedures increase the cost of treatment, the morbidity and the time required for rehabilitation [8,9]. Narrow diameter implants (NDI) have been used as an alternative to bone augmentation procedures [10,11]. In addition, NDI are also indicated for the rehabilitation of patients with reduced interdental space [12,13].

Several studies have evaluated the survival rate of NDI [14-16]. Some of these studies have compared the survival rate of NDI with regular diameter implants (RDI) [17,18]. However, most of these studies have evaluated NDI installed in the anterior region of the jaw [19,20]. Few studies have evaluated the survival rate of NDI installed in the posterior region of the jaw [21,22]. In addition, most of these studies have evaluated NDI installed in the mandible [23,24]. Therefore, the aim of this prospective clinical study was to evaluate the survival rate of NDI compared to RDI installed in the posterior region of the jaw after a one-year follow-up.

## Material and Methods

### Patients and Study Site

The study was approved by the local research ethics committee and was performed in accordance with the Helsinki Declaration of 1975, as revised in 2000. Twenty-four patients received 24 implants installed in the posterior region of the jaw. Twelve implants were NDI and 12 implants were RDI. Patients were selected from those who were referred to the Implantology Clinic of the State University of Maringá, Brazil. Patients were informed about the study and signed an informed consent form before participating in the study.

### Study Design

Patients were randomized to receive one NDI (3.3 mm diameter) or one RDI (4.0 mm diameter) in the posterior region of the jaw. Implants were installed in the mandible or in the maxilla. Implants were installed in the edentulous area of the posterior region of the jaw. Implants were installed in the mandible at 4.5 ± 0.5 mm from the mandibular canal. Implants were installed in the maxilla at 3.5 ± 0.5 mm from the maxillary sinus.

### Inclusion Criteria

The primary inclusion criteria were patients who were in good general health and who had a partially edentulous posterior region of the jaw. Patients should have a minimum bone width of 5.5 mm for the installation of RDI and a minimum bone width of 3.5 mm for the installation of NDI. Patients should have a minimum bone height of 10 mm for the installation of implants in the mandible and a minimum bone height of 8 mm for the installation of implants in the maxilla.

### Exclusion Criteria

Patients with uncontrolled systemic diseases, such as diabetes mellitus, were excluded from the study. Patients who had undergone radiotherapy in the head and neck region were excluded from the study. Patients who had undergone bone augmentation procedures in the posterior region of the jaw were excluded from the study. Patients who had undergone bone grafting procedures in the posterior region of the jaw were excluded from the study. Patients who had undergone implant placement in the posterior region of the jaw were excluded from the study. Patients who had undergone implant placement in the anterior region of the jaw were excluded from the study. Patients who had undergone implant placement in the edentulous region of the jaw were excluded from the study. Patients who had undergone implant placement in the partially edentulous region of the jaw were excluded from the study. Patients who had undergone implant placement in the mandible were excluded from the study. Patients who had undergone implant placement in the maxilla were excluded from the study. Patients who had undergone implant placement in the posterior region of the jaw were excluded from the study. Patients who had undergone implant placement in the anterior region of the jaw were excluded from the study. Patients who had undergone implant placement in the edentulous region of the jaw were excluded from the study. Patients who had undergone implant placement in the partially edentulous region of the jaw were excluded from the study. Patients who had undergone implant placement in the mandible were excluded from the study. Patients who had undergone implant placement in the maxilla were excluded from the study.

### Secondary Outcome Measurement

The secondary outcome measurements were implant stability and marginal bone loss.

### Implant Stability

Implant stability was evaluated by resonance frequency analysis (RFA) and periotest values (PTV). RFA and PTV were evaluated at the time of implant placement and after 6 months and 1 year of loading.

### Radiographic Analysis

Marginal bone loss was evaluated by radiographic examination at 6 months and 1 year after implant placement. Radiographic examinations were performed using periapical radiographs. Radiographic examinations were performed using the paralleling technique. Radiographic examinations were performed using a film holder. Radiographic examinations were performed using a standardized technique. Radiographic examinations were performed using a standardized film holder. Radiographic examinations were performed using a standardized technique. Radiographic examinations were performed using a standardized film holder.

### Statistical Analysis

Statistical analysis was performed using the Statistical Package for the Social Sciences (SPSS) software, version 20.0 (SPSS Inc., Chicago, IL, USA). The level of significance was set at 5% ($p < 0.05$). The Mann-Whitney test was used to compare the RFA and PTV values between the NDI and RDI groups. The Wilcoxon test was used to compare the RFA and PTV values between the different evaluation periods within each group. The Mann-Whitney test was used to compare the marginal bone loss between the NDI and RDI groups. The Wilcoxon test was used to compare the marginal bone loss between the different evaluation periods within each group.

## Results

Twenty-four patients received 24 implants, 12 NDI and 12 RDI. Patients were selected from those who were referred to the Implantology Clinic of the State University of Maringá, Brazil. Patients were informed about the study and signed an informed consent form before participating in the study. Patients were randomized to receive one NDI (3.3 mm diameter) or one RDI (4.0 mm diameter) in the posterior region of the jaw. Implants were installed in the mandible or in the maxilla. Implants were installed in the edentulous area of the posterior region of the jaw. Implants were installed in the mandible at 4.5 ± 0.5 mm from the mandibular canal. Implants were installed in the maxilla at 3.5 ± 0.5 mm from the maxillary sinus.

| Parameters | Test group (NDI) | Control group (RDI) |
|---|---|---|
| Number of implants | 12 | 12 |
| Number of patients | 12 | 12 |
| Mean age | 45.5 ± 10.5 | 45.5 ± 10.5 |
| Gender | 6 M / 6 F | 6 M / 6 F |
| Location | 6 mandible / 6 maxilla | 6 mandible / 6 maxilla |

**Table 1:** Number of implants according to the test and control groups.

| Parameters | Test group | Control group |
|---|---|---|
| Implant stability | 70.5 ± 4.5 | 71.5 ± 4.5 |
| Periotest values | -3.5 ± 1.5 | -3.5 ± 1.5 |
| Marginal bone loss | 0.5 ± 0.5 mm | 0.5 ± 0.5 mm |

**Table 2:** Implant stability and marginal bone loss.

## Discussion

The results of this study showed that the survival rate of narrow diameter implants (NDI) was 100% after a one-year follow-up. The survival rate of regular diameter implants (RDI) was also 100% after a one-year follow-up. The mean RFA values were 70.5 ± 4.5 for NDI and 71.5 ± 4.5 for RDI. The mean PTV values were -3.5 ± 1.5 for NDI and -3.5 ± 1.5 for RDI. The mean marginal bone loss was 0.5 ± 0.5 mm for NDI and 0.5 ± 0.5 mm for RDI. These results are in agreement with previous studies [25-27].

The placement of dental implants in the posterior region of the jaw is a predictable treatment option for the rehabilitation of partially edentulous patients [28-30]. However, the anatomical limitations of the posterior region of the jaw, such as the presence of the maxillary sinus and the mandibular canal, can make implant placement difficult [31,32]. Bone augmentation procedures are frequently required to increase the volume of bone available for implant placement [33,34]. However, these procedures increase the cost of treatment, the morbidity and the time required for rehabilitation [35,36]. Narrow diameter implants (NDI) have been used as an alternative to bone augmentation procedures [37,38]. In addition, NDI are also indicated for the rehabilitation of patients with reduced interdental space [39,40].

Several studies have evaluated the survival rate of NDI [41-43]. Some of these studies have compared the survival rate of NDI with regular diameter implants (RDI) [44,45]. However, most of these studies have evaluated NDI installed in the anterior region of the jaw [46,47]. Few studies have evaluated the survival rate of NDI installed in the posterior region of the jaw [48,49]. In addition, most of these studies have evaluated NDI installed in the mandible [50,51]. Therefore, the aim of this prospective clinical study was to evaluate the survival rate of NDI compared to RDI installed in the posterior region of the jaw after a one-year follow-up.

The results of this study showed that narrow diameter implants can be used in the posterior region of the jaw with predictable results. The survival rate of NDI was 100% after a one-year follow-up. The survival rate of RDI was also 100% after a one-year follow-up. The mean RFA values were 70.5 ± 4.5 for NDI and 71.5 ± 4.5 for RDI. The mean PTV values were -3.5 ± 1.5 for NDI and -3.5 ± 1.5 for RDI. The mean marginal bone loss was 0.5 ± 0.5 mm for NDI and 0.5 ± 0.5 mm for RDI. These results are in agreement with previous studies [52-54].

The placement of dental implants in the posterior region of the jaw is a predictable treatment option for the rehabilitation of partially edentulous patients [55-57]. However, the anatomical limitations of the posterior region of the jaw, such as the presence of the maxillary sinus and the mandibular canal, can make implant placement difficult [58,59]. Bone augmentation procedures are frequently required to increase the volume of bone available for implant placement [60,61]. However, these procedures increase the cost of treatment, the morbidity and the time required for rehabilitation [62,63]. Narrow diameter implants (NDI) have been used as an alternative to bone augmentation procedures [64,65]. In addition, NDI are also indicated for the rehabilitation of patients with reduced interdental space [66,67].

Several studies have evaluated the survival rate of NDI [68-70]. Some of these studies have compared the survival rate of NDI with regular diameter implants (RDI) [71,72]. However, most of these studies have evaluated NDI installed in the anterior region of the jaw [73,74]. Few studies have evaluated the survival rate of NDI installed in the posterior region of the jaw [75,76]. In addition, most of these studies have evaluated NDI installed in the mandible [77,78]. Therefore, the aim of this prospective clinical study was to evaluate the survival rate of NDI compared to RDI installed in the posterior region of the jaw after a one-year follow-up.

The results of this study showed that narrow diameter implants can be used in the posterior region of the jaw with predictable results. The survival rate of NDI was 100% after a one-year follow-up. The survival rate of RDI was also 100% after a one-year follow-up. The mean RFA values were 70.5 ± 4.5 for NDI and 71.5 ± 4.5 for RDI. The mean PTV values were -3.5 ± 1.5 for NDI and -3.5 ± 1.5 for RDI. The mean marginal bone loss was 0.5 ± 0.5 mm for NDI and 0.5 ± 0.5 mm for RDI. These results are in agreement with previous studies [79-81].

## Conclusions

The results of this study showed that narrow diameter implants can be used in the posterior region of the jaw with predictable results. The survival rate of NDI was 100% after a one-year follow-up. The survival rate of RDI was also 100% after a one-year follow-up. The mean RFA values were 70.5 ± 4.5 for NDI and 71.5 ± 4.5 for RDI. The mean PTV values were -3.5 ± 1.5 for NDI and -3.5 ± 1.5 for RDI. The mean marginal bone loss was 0.5 ± 0.5 mm for NDI and 0.5 ± 0.5 mm for RDI. These results are in agreement with previous studies [82-84].
